## Lecture No 9

# AUTHENTICATION AND MESSAGE INTEGRITY

# Authentication

- ❑ Authentication is the process of proving one's identity to someone else
- ❑ There are three main ways of authenticating an individual:
  - ❑ Something you know: A password, cryptographic key, or the correct answer to a challenge-response test
  - ❑ Something you own: A physical key, security card or badge, or a one-time password generator
  - ❑ Something you are: Some biometric measurement (facial features, fingerprint, retina scan, voice print, and so on)
- ❑ We need an authentication protocol during communication when direct proof cannot be given

# Authentication

## A First Attempt

- ❑ Goal: Bob wants Alice to “prove” her identity to him
- ❑ Protocol 1.0: Alice says “I am Alice”

Failure scenario??

# Authentication

## A First Attempt

- ❑ Goal: Bob wants Alice to “prove” her identity to him
- ❑ Protocol 1.0: Alice says “I am Alice”

Failure scenario??

On a communication channel, Bob can not “see” Alice, so Trudy simply declares herself to be Alice

# Authentication

## Another try

- ❑ Goal: Bob wants Alice to “prove” her identity to him
- ❑ Protocol 2.0: Alice says “I am Alice” in an IP packet containing her source IP address

Failure scenario??

# Authentication

## Another try

- ❑ Goal: Bob wants Alice to “prove” her identity to him
- ❑ Protocol 2.0: Alice says “I am Alice” in an IP packet containing her source IP address

Alice's  
IP address

“I am Alice”

Failure scenario??

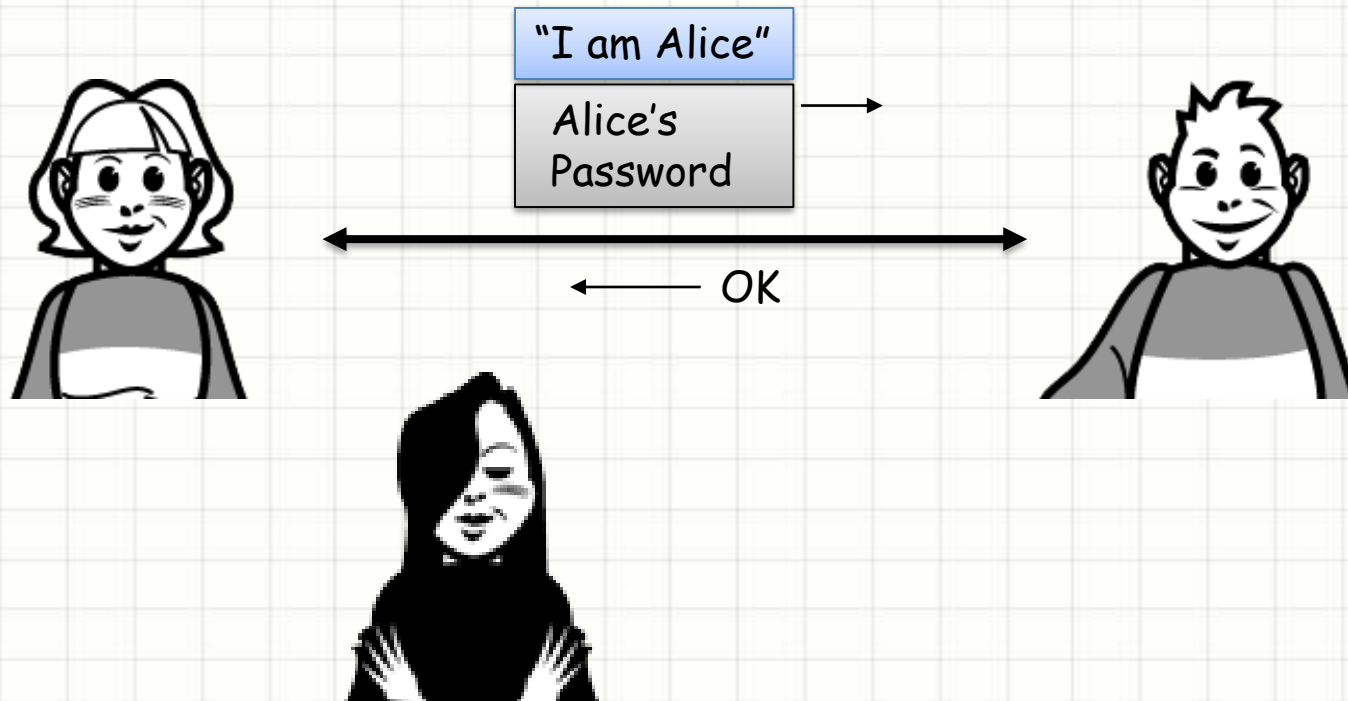

Trudy can create a packet  
“spoofing” Alice's IP address

# Authentication

## Another try

- ❑ Goal: Bob wants Alice to “prove” her identity to him
- ❑ Protocol 3.0: Alice says “I am Alice” and sends her secret password to “prove” it

Failure scenario??

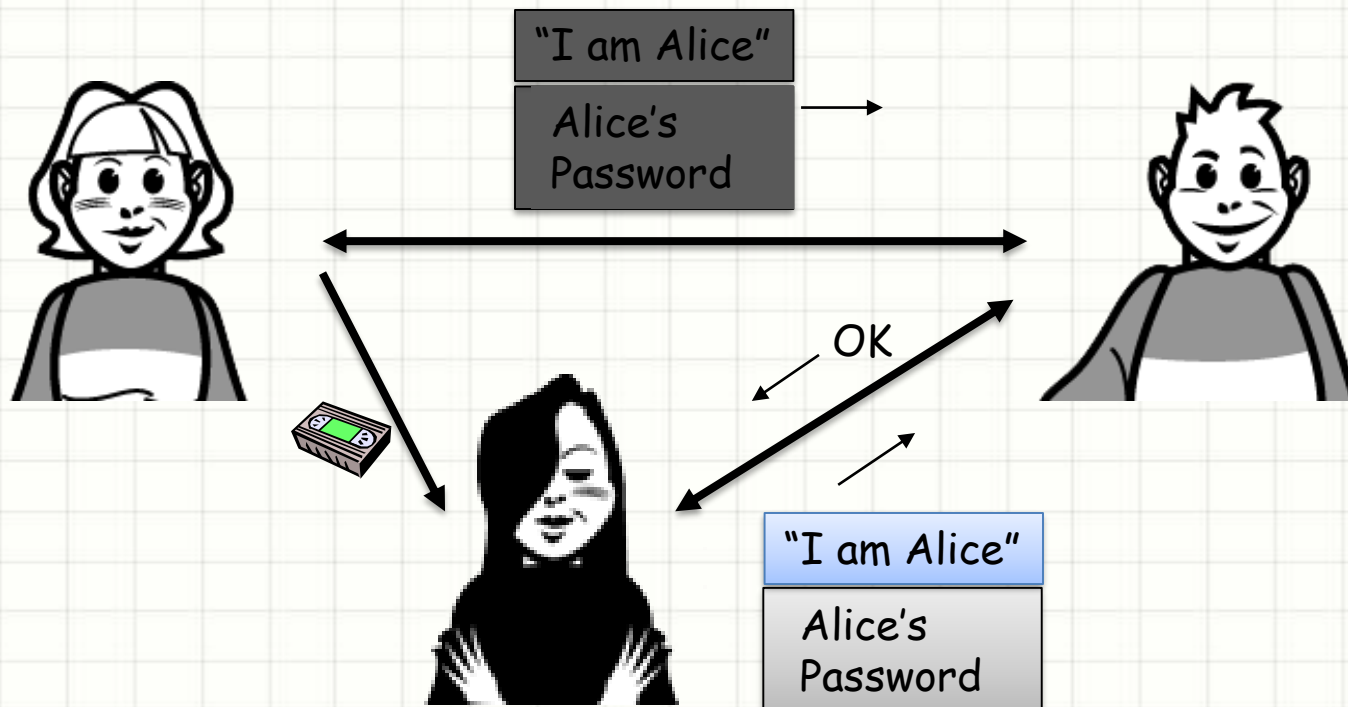

# Authentication

## Another try

- ❑ Goal: Bob wants Alice to “prove” her identity to him
- ❑ Protocol 3.0: Alice says “I am Alice” and sends her secret password to “prove” it

Failure scenario??

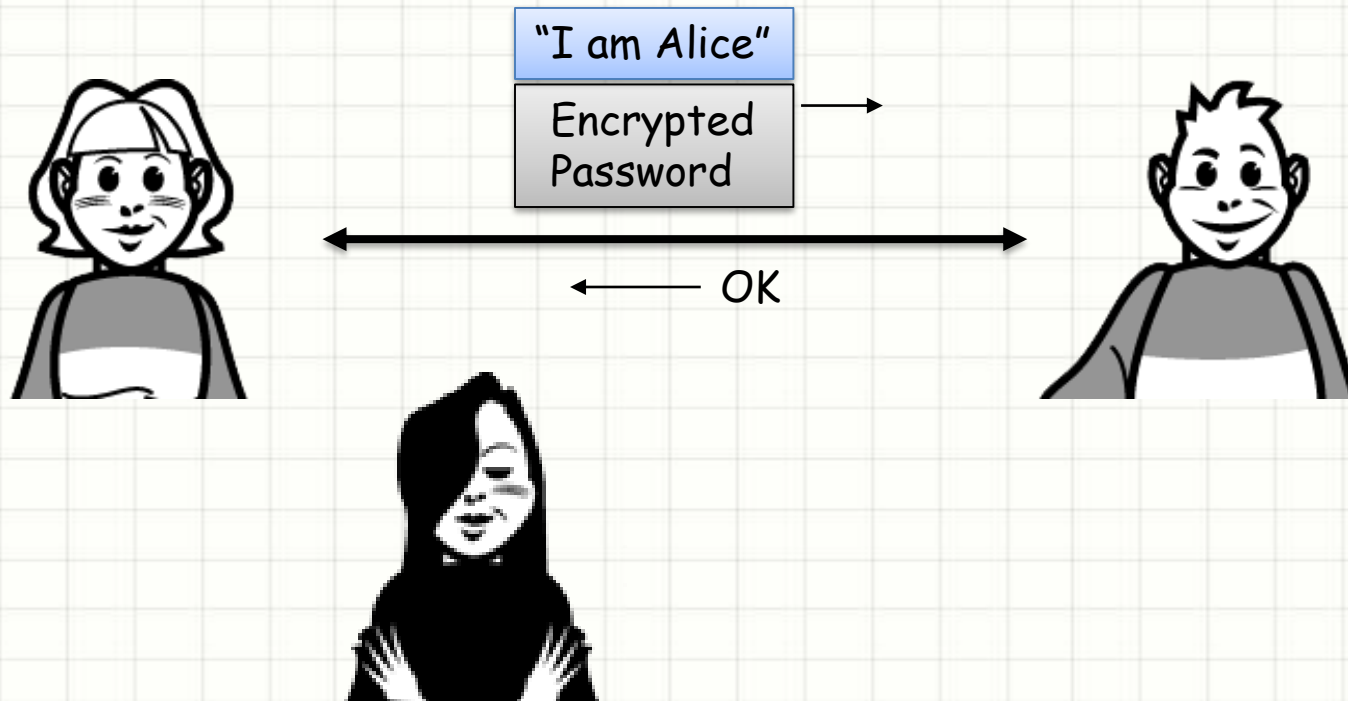

Playback attack: Trudy records Alice's packet and later plays it back to Bob

# Authentication

## Better try

- ❑ Goal: Bob wants Alice to “prove” her identity to him
- ❑ Protocol 3.1: Alice says “I am Alice” and sends her encrypted secret password to “prove” it

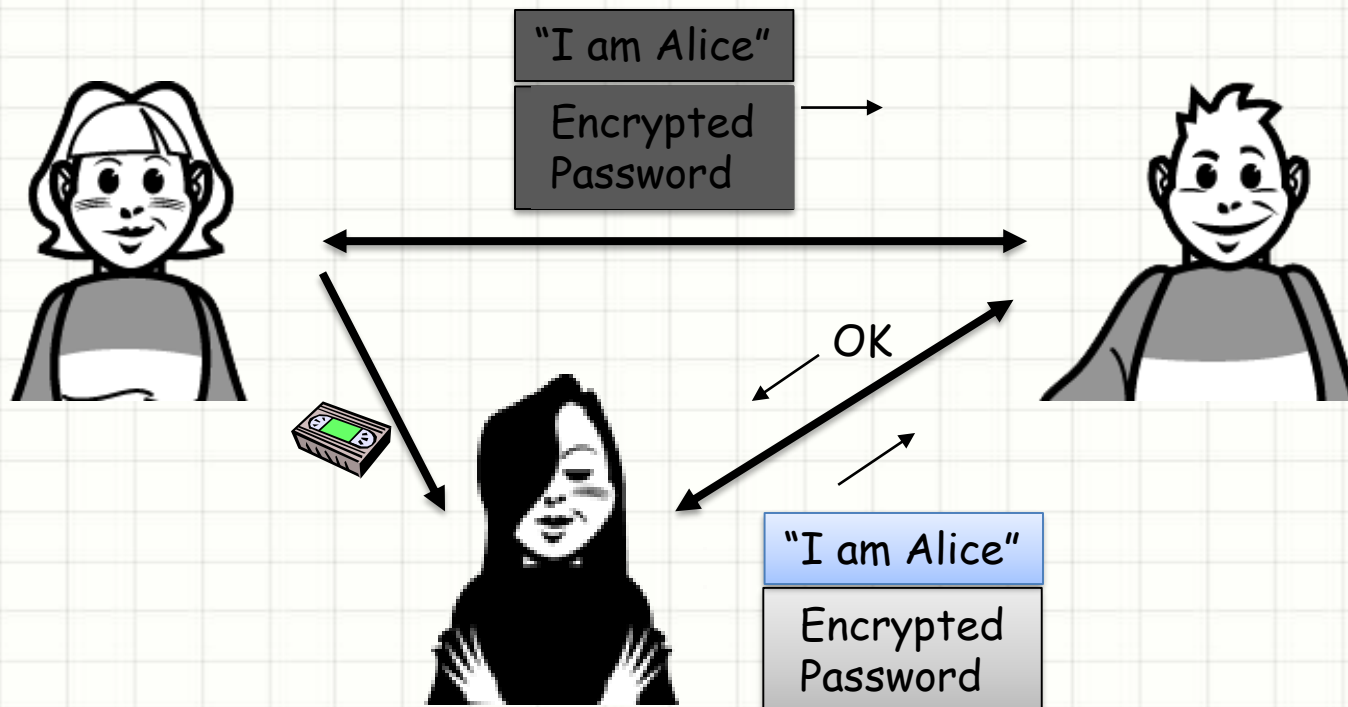

Failure scenario??

# Authentication

## Better try

- ❑ Goal: Bob wants Alice to “prove” her identity to him
- ❑ Protocol 3.1: Alice says “I am Alice” and sends her encrypted secret password to “prove” it

Failure scenario??

Record and playback  
still works!

# Authentication

## One More Try

- ❑ Goal: Bob wants Alice to “prove” her identity to him
- ❑ Nonce: number (timestamp) used only once—in-a-lifetime
- ❑ Protocol 4.0: To prove Alice “live”, Bob sends Alice nonce, N. Alice must return N, encrypted with shared secret key

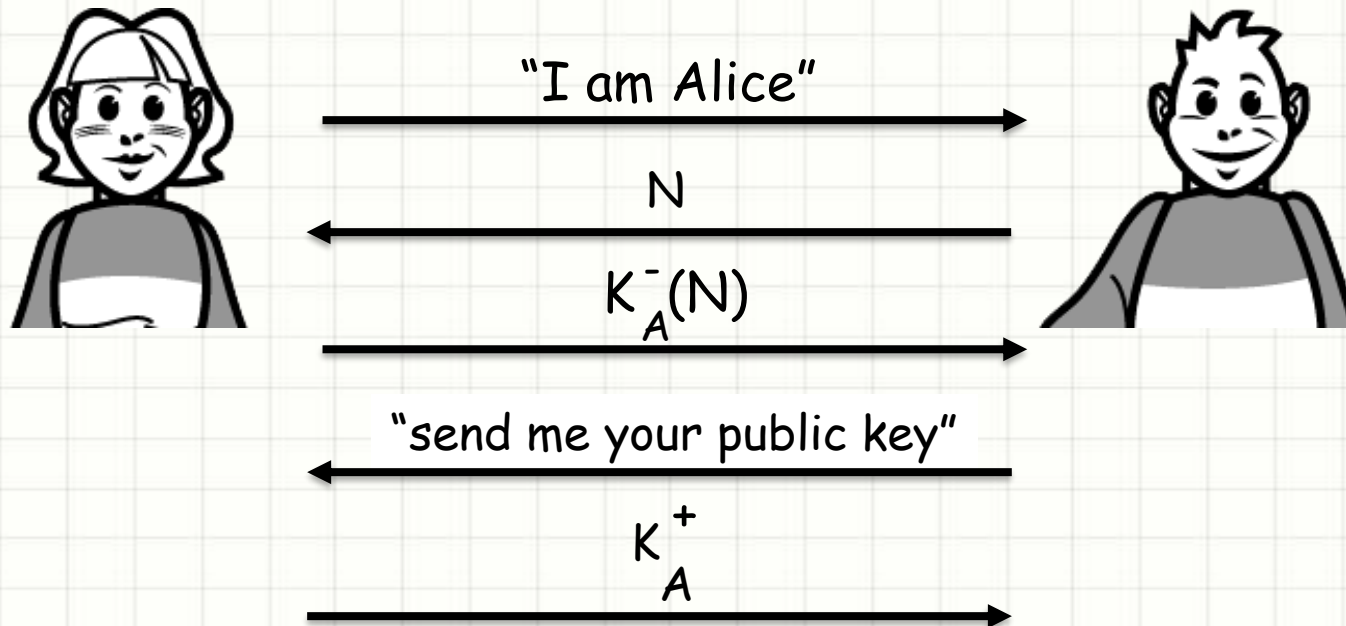

Failures, drawbacks?

# Authentication

- ❑ Protocol 4.0 requires shared symmetric key
- ❑ Can we authenticate using public key techniques?
- ❑ Protocol 5.0: use nonce, public key cryptography

Failures, drawbacks?

As only Alice has the private key, Bob knows that ONLY she has encrypted  $N$ . Bob can read  $N$  as,

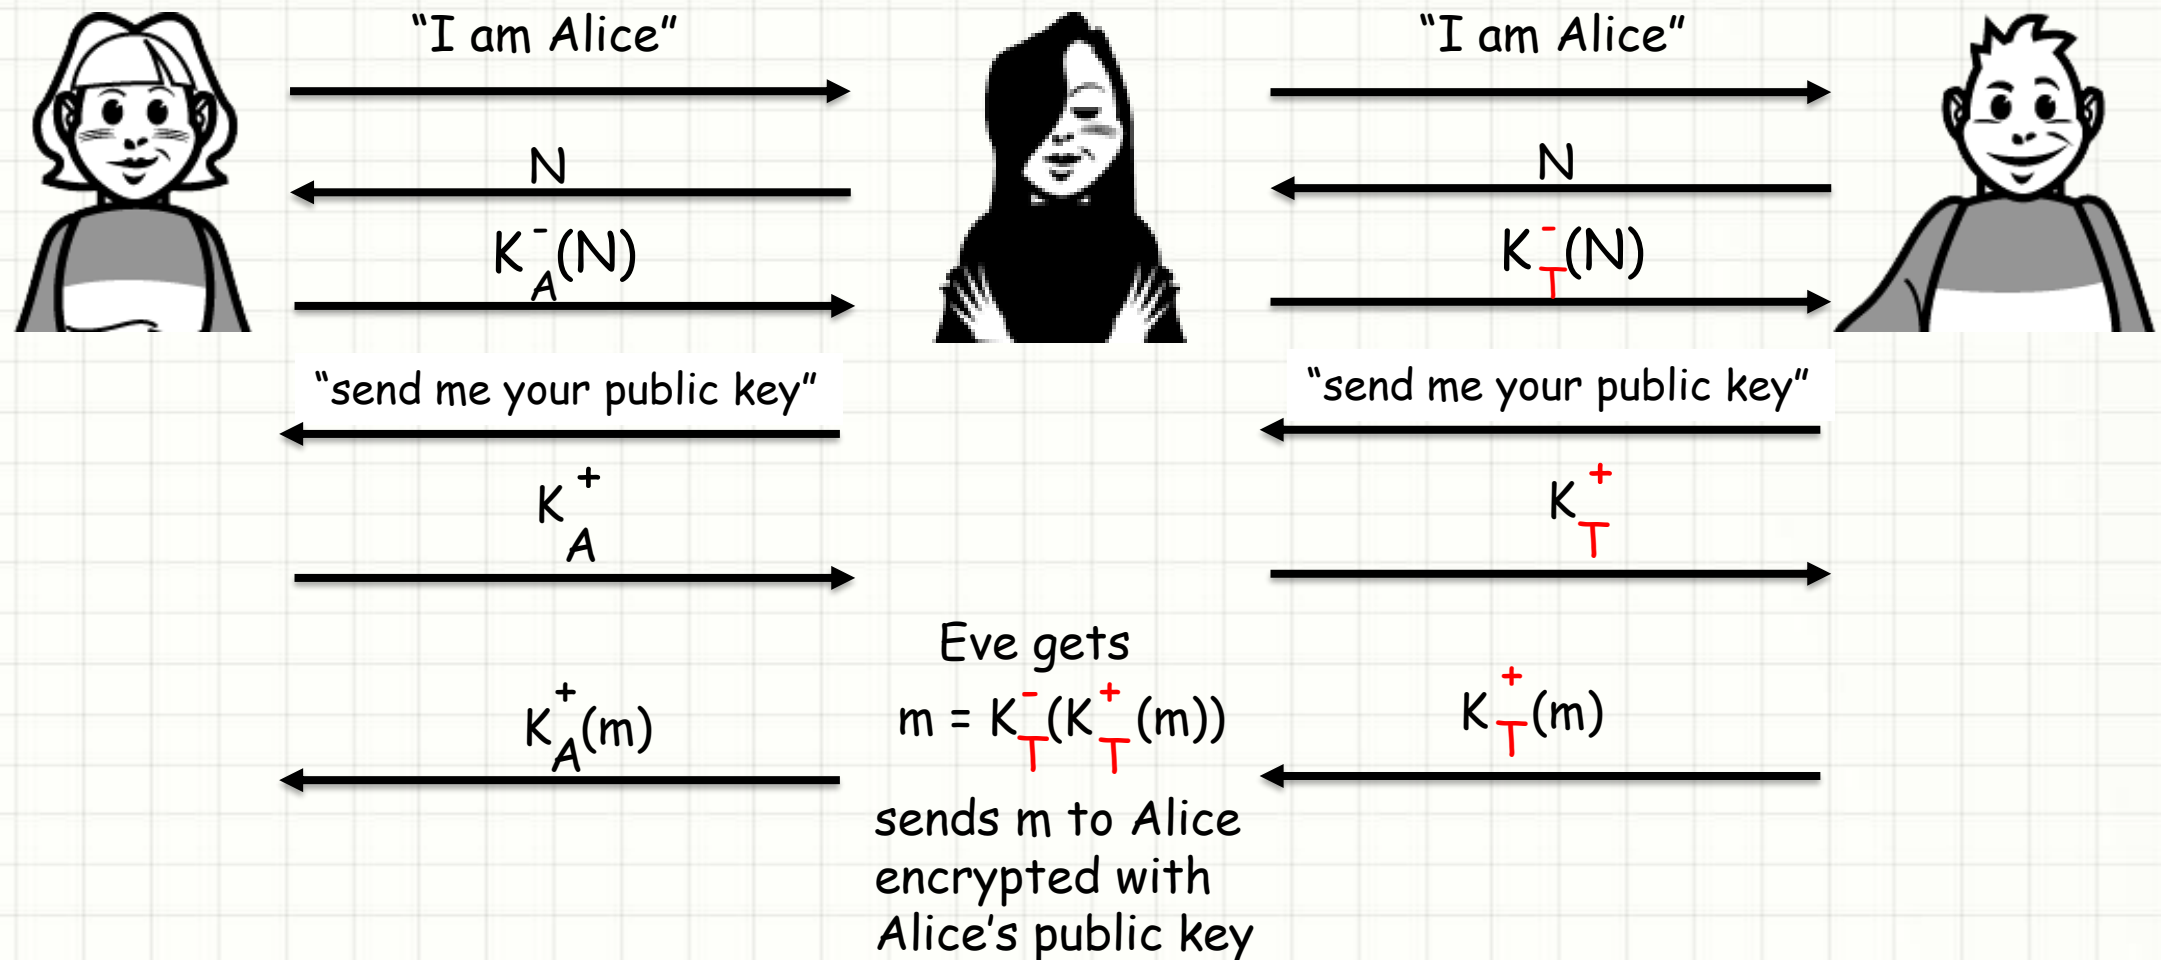

$$K_A^+(K_A^-(N)) = N$$

# Authentication

- ❑ Protocol 5.0: Security Hole
- ❑ Man in the middle attack: Eve poses as Alice (to Bob) and as Bob (to Alice)

# Authentication

Man in the middle attack: Eve poses as Alice (to Bob) and as Bob (to Alice)

Difficult to detect:

- ☐ Bob receives everything that Alice sends, and vice versa
- ☐ Problem is that Eve receives all messages as well!

Note: The problem was one of key distribution

- ☐ If Bob knew or could securely obtain Alice's public key, there would have been no problem!

# Authentication

## Hybrid Secret-Public Key Authentication

- ❑ As discussed earlier, the idea is to use public key cryptography to negotiate a symmetric session key for communication
- ❑ We must have mutual authentication to ensure the session key can be trusted
- ❑ Both Alice and Bob must agree that they are in fact talking to their counterpart
- ❑ In this case, we will assume that Alice and Bob already know each other's public keys
- ❑ We will look at key distribution and certification very shortly

# Authentication

## Hybrid Secret-Public Key Authentication

"I am Alice",

$$K_B^+(K_A^-(K_S, N))$$

$$K_A^+(K_B^-(K_S))$$

$K_S(\text{message 1})$

$K_S(\text{message 2})$

# Authentication

## Hybrid Secret-Public Key Authentication

- ❑ In her message to Bob, Alice identifies herself, and sends a message that only Bob can decrypt with his private key
  - ❑ After decrypting the outer message, the inner message can only be decrypted with Alice's public key, proving that she sent it
  - ❑ This contains the new session key  $K_S$  and a nonce to ensure freshness
  
- ❑ Bob sends a response to Alice that only Alice can decrypt with her private key
  - ❑ After decrypting the outer message, the inner message can only be decrypted with Bob's public key, proving that he sent it
  - ❑ This contains the session key again. If it matches what she sent originally, then they are mutually authenticated and can use the key

# Message Integrity

- ❑ Bob receives message from Alice, and so Bob wants to ensure:
  - ❑ That the message originally came from Alice
  - ❑ That the message not changed since sent by Alice
- ❑ This is what ensuring message integrity is all about
- ❑ There are several ways to go about doing this
- ❑ Of course, some are better than others

# Message Integrity

## Message Checksum

- ❑ A checksum is a function calculated over input data to determine if the data has been altered or corrupted
- ❑ Checksums are simple to fool, as it is not difficult to alter data in such a way that the same checksum is produced
- ❑ Since checksums themselves are not protected, they can be changed after data has been altered anyways
- ❑ Checksums, however, are easy to calculate and offer a very basic integrity check

# Message Integrity

## Message Checksum (Example)

- ❑ Checksums used in data packets of the Internet protocol suite are a good example
- ❑ They provide some protection against corruption, but as seen below, it is quite easy to have different messages produce the same checksums

| <u>message</u> | <u>ASCII format</u> |
|----------------|---------------------|
| I O U 1        | 49 4F 55 31         |
| 0 0 . 9        | 30 30 2E 39         |
| 9 B O B        | 39 42 D2 42         |
|                | <hr/>               |
|                | B2 C1 D2 AC         |

| <u>message</u> | <u>ASCII format</u> |
|----------------|---------------------|
| I O U <u>9</u> | 49 4F 55 <u>39</u>  |
| 0 0 . <u>1</u> | 30 30 2E <u>31</u>  |
| 9 B O B        | 39 42 D2 42         |
|                | <hr/>               |
|                | B2 C1 D2 AC         |

different messages but identical checksums!

# Message Integrity

## Message Sequence Number

- ❑ Another basic integrity check is a sequence number, which gives the position of a message relative to a larger stream of messages
- ❑ Sequence numbers can be used to determine if messages have been inserted or deleted, but not if they have been modified
- ❑ Since sequence numbers can be forged like checksums, they only provide minimal integrity protection on their own

# Message Integrity

## Message Digests (MD)

- ❑ A special kind of checksum produced using cryptographic means
  - ❑ Also referred to as cryptographic checksums
- ❑ Typically produced as a hash-code from a one-way function that is difficult to reverse or predict
- ❑ Given a message digest  $x$  and hash function  $H$ , it should be computationally infeasible to find a message  $m$  such that  $H(m) = x$
- ❑ This function takes the entire input and reduces it to a small value of fixed length (typically 128 to 512 bits in length)

# Message Integrity

## Message Digests (MD)

- ❑ Since modifications to the input data changes the message digest, it is practically impossible to alter a message and still have a matching digest
- ❑ However, there is nothing preventing modifying the digest as well to reflect any alterations to the original message
- ❑ The solution is to produce a more secure digest, protected by a secret of some kind, referred to as a **message authentication code**

# Message Integrity

## Message Authentication Codes (MAC)

There are a couple of approaches to creating message authentication codes

- ❑ One approach is to produce an encrypted digest, by providing a key or password to the digest function
- ❑ Without this key or password, modifying the digest itself is no longer an option
  
- ❑ Another approach is to embed a shared secret called an authentication key in with the message before being passed into the digest hash function
- ❑ Without knowing this shared secret on the receiving end, the hash function cannot reproduce the same message authentication code

# Message Integrity

## How Hash Functions Work

# Message Integrity

## Basic uses of Hash functions

- ☐ User authentication
- ☐ Message authenticity
- ☐ Compact file identifiers
- ☐ Used in digital signatures

# Message Integrity

## Hash Functions

- ❑ To be useful for message integrity, a hash function  $H$  must have the following properties:
  1.  $H$  can be applied to a block of data of any size
  2.  $H$  produces a fixed-length output
  3.  $H(x)$  is relatively easy to compute for any given  $x$
  4. For any given code  $h$ , it is computationally infeasible to find  $x$  such that  $H(x) = h$
  5. For any given block  $x$ , it is computationally infeasible to find  $y \neq x$  with  $H(y) = H(x)$  (referred to as weak collision property)
  6. It is computationally infeasible to find any pair  $(x, y)$  such that  $H(x) = H(y)$  (referred to as strong collision property)

# Message Integrity

- ❑ The last property protects against a sophisticated class of attack known as the **birthday attack**

## Message Digests: Hash Function Algorithms

- ❑ MD5 hash function widely used (RFC 1321)
  - ❑ Computes 128-bit message digest in 4-step process
- ❑ SHA-1 is also used, US standard [NIST, FIPS PUB 180-1]
  - ❑ 160-bit message digest
- ❑ Issues in both MD5 and SHA-1 have been found in recent years though
- ❑ These algorithms are now being phased out more quickly in favor of other, newer approaches like SHA-2, and so on

# Message Integrity - Secure Hash Algorithm

- ❑ **Secure Hash Algorithm (SHA)** was developed by the National Institute of Standards and Technology (NIST) and published as FIPS 180 in 1993
- ❑ Revised as FIPS 180-1 in 1995, generally referred to as SHA-1
- ❑ Based on the MD4 algorithm that was developed by Ron Rivest at MIT
- ❑ MD4 (and MD5) produce a 128 bit message digest whereas SHA-1 produces a 160 bit
- ❑ In 2002, NIST produced a revised version of the standard, FIPS180-2, that defined three new versions of SHA
  - ❑ SHA-256, SHA-384, and SHA-512, have hash value lengths of 256, 384, and 512 bits respectively

# Message Integrity - Secure Hash Algorithm

- ❑ SHA-1 takes as input a message and produces as output a 160 bit message digest, input is processed in 512-bit blocks

Digest generation using MD5 (equally applicable to SHA-1 with 160 bits)

# Message Integrity - Secure Hash Algorithm

## SHA Overview - overall processing of a message to produce a digest

- ❑ Pad message so its length is  $448 \bmod 512$
- ❑ Append a 64-bit length value to message
- ❑ Initialize 5-word (160-bit) buffer (A,B,C,D,E) to
  - ❑ (67452301,efcdab89,98badcfe,10325476,c3d2e1f0)
- ❑ Process message in 16-word (512-bit) chunks:
  - ❑ expand 16 words into 80 words by mixing & shifting
  - ❑ use 4 rounds of 20 operations on message block & buffer
  - ❑ add output to input to form new buffer value
- ❑ Output hash value is the final buffer value

# Message Integrity - Secure Hash Algorithm

- ❑ SHA-1 compression function (processing of a single 512-bit block)

# Message Integrity - Secure Hash Algorithm

## SHA-1 verses MD5

- ☐ Brute force attack is harder (160 vs 128 bits for MD5)
  - ☐ Not vulnerable to any known attacks (compared to MD4/5)
  - ☐ A little slower than MD5 (80 vs 64 steps)
  - ☐ Both designed as simple and compact
- 
- ☐ In 2005, an attack was successful, in which two separate messages deliver the same SHA-1 hash using  $2^{69}$  operations
  - ☐ NIST announced the intention to phase out SHA-1 and move to a reliance on the other SHA versions by 2010

# Message Integrity – The Birthday Attack

- ❑ The Birthday attack makes use of what's known as the Birthday Paradox to try to attack cryptographic hash functions
- ❑ The birthday paradox can be stated as follows:  
"What is the minimum value of  $k$  such that the probability is greater than 0.5 that at least two people in a group of  $k$  people have the same birthday?"
- ❑ It is a probability problem that deals with the probability of at least one pair of people in a group of  $n$  people that share the same birthday
- ❑ It turns out that the answer is **23 (and not 183)**, which is quite a surprising result

# Message Integrity – The Birthday Attack

- ❑ In other words, if there are 23 people in a room, the probability that two of them have the same birthday is approximately 0.5
- ❑ If there are 100 people (i.e.  $k=100$ ) then the probability is .9999997, i.e. you are almost guaranteed that there will be a duplicate
- ❑ Although this is the case for birthdays we can generalize it for  $n$  equally likely values (in the case of birthdays  $n=365$ )

# Message Integrity – The Birthday Attack

- So the problem can be stated like this;

*Given a random variable that is an integer with uniform distribution between **1** and **n** and a selection of **k** instances (**k** ≤ **n**) of the random variable, what is the probability **P(n, k)**, that there is at least one duplicate?*

It has been found that;

- $K = 1.18\sqrt{n} \approx \sqrt{n}$
- For  $n = 365$ , almost equal to 23

# Message Integrity – The Birthday Attack

- ❑ Now let's look at this in terms of hash codes
- ❑ Remember a hash code is a function that takes a variable length message  $M$  and produces a fixed length message digest
- ❑ Assuming the length of the digest is  $m$  then there are  $2^m$  possible message digests
- ❑ However (normally), because the length of  $M$  will generally be greater than  $m$  this implies that more than one message will be mapped to the same digest
- ❑ The idea is to make it computationally infeasible to find two messages that map to the same digest (strong collision property)

# Message Integrity – The Birthday Attack

- ❑ If we apply  $k$  random messages to our hash code what must the value of  $k$  be so that there is the probability of 0.5 that at least one duplicate (i.e.  $H(x) = H(y)$  will occur for some inputs  $x, y$ )?
  - ❑ This is the same as the question we asked about the birthday duplicates
- ❑ Answer is simple;  
 $k = \sqrt{2^m} = 2^{m/2}$  (as  $n$  here is  $2^m$ )

# Message Integrity – The Birthday Attack

- ❑ If we use a 64-bit hash code then the level of effort required is only on the order of  $2^{m/2} = 2^{64/2} = 2^{32}$  which is clearly not sufficient to withstand today's computational systems

# Message Integrity – The Birthday Attack

- ❑ Given  $h$ , attacker computes  $m, m'$  such that  $h(m) = h(m')$ 
  - ❑ generate  $t = 2^{n/2}$  variations on  $m$  (all of which convey essentially the same meaning)
  - ❑ generate a minor modification  $m'$  of  $m$  (equal in number as that of  $m$ )
  - ❑ The two sets of messages ( $m, m'$ ) are compared to find a pair of messages that produce the same hash code ( $h$ )
  - ❑ repeat the above step until a match is found (this is expected after  $t$  steps)
- ❑ Attacker gives  $m$  to the 'source' to hash-then-sign
- ❑ consequences: a signature on  $m$  is also a valid signature on  $m'$
